A cirrhotic rat model was established by administration of carbon tetrachloride (CCl4). NO production was determined by measuring the cGMP level and cGMP/cAMP ratio. The results were as follows: (1) NO production was decreased in the CCl4 group compared with the control group. (2) L-Arginine (L-Arg) treatment significantly increased NO production in the CCl4 group compared with the CCl4 group. (3) Treatment of endothelial cells with L-Arg significantly increased NO production. Our results suggest that the decreased NO production in cirrhosis might be caused by the decreased production of L-Arg in the CCl4-treated rats. The decrease in NO production in cirrhotic rats might be reversed by treatment with L-Arg.The present invention is directed to a laser ablation/ablation apparatus for use in transferring information (e.g. data) onto a surface of an information-bearing medium, or onto a glass microchip. More particularly, the invention is directed to such a device which is automatically controlled. Conventional laser ablation/ablation devices of the type referred to above include a laser which is capable of emitting light of sufficient intensity to ablate or remove particles from the surface of an information-bearing medium. Such a device further includes one or more optical elements which are suitable for focussing the light to the surface of the information-bearing medium. The apparatus typically comprises a hand-held housing, in which the laser and the focussing optics are located. A suitable controller is also located within the housing, and is coupled to the laser and the focussing optics. The controller can be connected to a remote computer or to a laser marking system. Such a laser marking system, for example, can be a laser plotter which generates a desired marking pattern on the surface of the information-bearing medium (e.g. sheet glass, film or other print medium). The focussing optics include 2d92ce491b
