Modern gas turbine engines have developed over the years and continue to experience significant advances in performance, efficiency and reliability. Today, some gas turbine engines have been developed that provide a combined cycle operation (CC) wherein hot gas from the combustion process of a gas turbine engine is used to heat a separate expander steam turbine for the generation of electricity. The number of gas turbine engines used for generating electricity has increased with the energy demands of society. Accordingly, there is a need for a gas turbine engine that is more efficient at providing electrical energy. In conventional gas turbine engines, hot gas flow from a compressor is mixed with fuel and ignited to generate high pressure combustion gases for powering the engine. The combustion gases pass through one or more stages of static vanes and rotary blades and accelerate in the turbine section of the engine. The hot combustion gases are directed against a series of stationary vanes (or stator vanes) and rotating blades (or rotor blades) to impart a torque onto a shaft. The shaft is connected to various equipment such as an electrical generator to produce electricity. The efficiency of the engine is affected by the leakage of hot gas flow. Typically, the gaps or clearances between rotor blades and the casing are designed to be smaller than the vanes. The maximum amount of flow leakage is around the sides of the rotor blades through the gaps between the blades and the casing. One area of improvement in the design of gas turbine engines is directed to the construction of the rotor blade. The thermal energy of the hot combustion gases flowing through the engine is transferred through the rotor blades and rotor disk to a cooling air flow. In order to reduce the temperature of the 1cb139a0ed
